3 cases that ViewModel is a must

1-Security: To protect sensitive data like Salary or IsAdmin from being displayed or modified by the user by including only the required properties in the ViewModel.

2- Combining Multiple Models: When a View needs data from more than one Model, we use a ViewModel to combine them into one object.

3- Customizing View Data: When we need to send only specific properties to the View or add properties that are not in the original Model.
